FAM161A (660 aa) aligns with Titin (33,800 aa) at 198 columns in 120 sites separated fairly evenly across 560 residues. Aligned residues in FAM161A are enriched for charged side-chains (DEKR, 52% included), but exclude small, polar amino acids (ACGST, 8% included).

B. Low complexity regions in FAM161A.

The low complexity filter in PSI-BLAST at NCBI identified nine low complexity blocks (bold, underlined, lower case) containing 147 residues (mainly charged).

Supplementary Figure S3

The wedge helix of Tpx2 is buried deeply in the pocket formed by four tubulin monomers

Views of Tpx2 bound to four tubulins (blue, yellow, green and pink), showing: A. the wedge binding into the pocket on the front of the tubulin polymer with such penetration that it partly crosses the mid-line between the front and back of the polymer (dotted line, right hand panel). B: Close up of region in box in part A, showing surface of all chains, with wedge coloured: red for helix and grey for extended loop. Space at its C-terminus is indicated by asterisks.

Sequences predicted to be helical were aligned by MAFFT, and coloured to show residue properties (Zappo scheme). Hydrophobic moments (μH), indicating degree of amphipathicity were obtained for each full helix from Heliquest (Gautier *et al.*, 2008).

Supplementary Figure S5

Sequences in amphipathic helices in the FAM161 family

Sequences of predicted amphipathic helices in FAM161 proteins were extracted from multiple sequence alignments, either (A) with all FAM161s (from the 9th iteration of HHblits), or (B) with FAM161B only (from BLAST *i.e.* no iterations and e-value cut-off set to exclude any proteins annotated as FAM161A). Residues are coloured by the Clustal scheme. Consensuses of the predicted helices are summarised at the bottom, and are coloured as in Figure S3B.

Supplementary Figure S6

Variation of *Tpx2* ridge and wedge sequences across species.

A multiple sequence alignment of >1200 *Tpx2* homologues created in HHblits was clipped down to the region aligning with human 297-375, and reduced to 48 sequences by excluding redundant and partial sequences (with >10 gaps across residues). The alignment was then reduced further to residues 297-350. The pink and blue boxes in the alignment indicate the human ridge and wedge sequences. Motifs below shows consensus sequences across the ridge (10 aa) and wedge (14 aa, 10 of which are predicted to be in a helix), with greater conservation indicated by capitals and bold; colouring: hydrophobic (\emptyset) – black; A/P/G: grey; K/R – blue; D/E – red; \pm mixed KRDEQN, predominant charge either red or blue; S/T–green. The spacing of hydrophobic residues in the wedge (\emptyset positions 1/5/8) is indicated by pink positions along a helix. Black arrows indicate the conserved F (334 in human) in the *Tpx2* wedge. Blue arrows indicate a protist *Tpx2* where the wedge lacks a terminal proline (blue box). Alignment coloured with Clustal scheme.
